

There are two kinds of homeowners on a hot July afternoon: the ones whose air conditioning is humming along quietly, and the ones standing over a thermostat, pressing buttons like they are trying to unlock a submarine.

If your HVAC system has started making expensive noises, blowing lukewarm air, short cycling, leaking water, tripping breakers, or generally acting like it has joined a small rebellion, you are probably facing the old question: should you repair it or replace it?

It sounds simple until someone hands you a repair estimate for \$1,100 on a 13-year-old air conditioner. Suddenly the math starts wearing a fake mustache. A repair might buy you a few more seasons. A replacement might save money over time. Or it might be an oversized solution to a small problem, like buying a new truck because the cup holder broke.

The right answer depends on age, efficiency, repair history, comfort, safety, energy costs, parts availability, and your tolerance for surprise invoices. It also depends on whether the technician diagnosing the system knows what they are doing. A good HVAC pro should be part mechanic, part detective, part therapist for frustrated homeowners.

Let's sort through the decision without scare tactics, sales fog, or pretending every furnace over ten years old belongs in a museum.

Start with the symptom, not the sales pitch

A struggling HVAC system rarely fails for "one" reason in the way a light bulb fails. Heating and cooling equipment is a network of electrical components, motors, refrigerant circuits, airflow pathways, drain lines, burners, sensors, controls, and safety switches. One weak part can make another look guilty.

For example, an air conditioner that is not cooling might have a failed capacitor, a dirty condenser coil, a low refrigerant charge, a failing compressor, a clogged filter, a bad blower motor, or ductwork leaking into an attic hot enough to bake bread. Those are not equal problems. One might cost less than a family dinner out. Another might make replacement worth discussing.

The same goes for heating. A furnace that will not fire could have a dirty flame sensor, a cracked heat exchanger, a blocked intake, a failed control board, or a gas pressure issue. One is a basic service call. One is a serious safety concern. One is the sort of thing you do not want diagnosed by a cousin who once fixed a toaster.

So before you decide repair versus replacement, you need a diagnosis that explains the failure, not just a quote that says "unit old." Age matters. It does not get to be the only witness in the trial.

The age of the system matters, but it does not make the decision by itself

Most central air conditioning systems last somewhere around 12 to 17 years, depending on climate, installation quality, maintenance, usage, and luck. Furnaces often last longer, commonly 15 to 25 years. Heat pumps usually land closer to air conditioners because they work during both heating and cooling seasons.

Those numbers are not warranties from the universe. I have seen 9-year-old systems ruined by bad installation and 22-year-old furnaces still running with the stubborn dignity of a diner waitress on a double shift. Still, age gives you a useful starting point.

A 5-year-old air conditioner with a failed capacitor is almost always a repair candidate. A 16-year-old air conditioner with a failed compressor, poor efficiency, and a history of refrigerant leaks deserves a replacement conversation. A 20-year-old furnace with a cracked heat exchanger should not be patched together with hope and duct tape, especially since heat exchanger failure can create carbon monoxide risk.

The mistake homeowners make is treating age as either irrelevant or absolute. It is neither. Think of it like a car. You do not junk a reliable 8-year-old car because it needs tires. But if your 18-year-old car needs a transmission, burns oil, has failing brakes, and smells faintly like crayons, you stop pretending the next repair is the last one.

The repair cost rule is helpful, not holy scripture

You may hear the “\$5,000 rule” or a similar formula: multiply the age of the system by the repair cost, and if the result exceeds \$5,000, consider replacement. So if a 12-year-old AC needs an \$800 repair, 12 times 800 equals 9,600, which points toward replacement.

That rule has value because it forces you to think beyond the immediate invoice. It is also a blunt instrument. Like many blunt instruments, it can be useful, but you should not use it for surgery.

A better version is to compare the repair cost against the realistic remaining life of the system and the cost of replacement. If the repair is small and the system is otherwise healthy, repair it. If the repair is large, the system is old, and another major component is likely to fail soon, replacement may be the less painful option.

Here is a short way to frame it:

Situation	Repair usually makes sense	Replacement deserves serious thought	--- --- ---	System age	Under 8 years	Over 12 to 15 years for AC or heat pump, over 18 years for furnace	Repair cost	Minor to moderate	30% to 50% of replacement cost	Repair history	First notable issue	Repeated breakdowns in recent seasons	Comfort	Home still heats and cools evenly	Rooms are uneven, humid, noisy, or drafty	Efficiency	Utility bills are stable	Energy use keeps climbing without lifestyle changes
-----------	----------------------------	--------------------------------------	-------------	------------	---------------	--	-------------	-------------------	--------------------------------	----------------	---------------------	---------------------------------------	---------	-----------------------------------	---	------------	--------------------------	---

That table is not a verdict. It is a flashlight. Use it to see where you are standing.

When repair is the sensible move

Repair often makes perfect sense, and not just because it costs less today. If your system has been reliable, is not terribly old, and the failure is isolated, fixing it can be the smartest use of money.

Capacitors, contactors, ignitors, flame sensors, blower belts in older systems, clogged condensate drains, thermostats, and some control components are common repair items. They fail. That does not mean the whole system is doomed. Even good equipment has wear parts.

A clogged condensate drain, for example, can shut down an air conditioner or cause water damage around the indoor unit. That can look dramatic, especially if there is water around the furnace or air handler. But in many cases, proper drain clearing, cleaning, and a float switch check solve the issue. It may feel like an HVAC emergency, but it is not necessarily a replacement situation.

The same is true for poor airflow caused by a dirty filter or matted evaporator coil. I have seen homeowners convinced their AC was dying when the real culprit was a filter so clogged it looked like it had been pulled from a lint trap in a sweater factory. Filters are cheap. Compressors are not. Start with airflow.

Repair is also reasonable when you are planning to move soon, as long as the system can be restored safely and reliably. Buyers may still ask about age during inspection, but replacing an entire system right before selling does

not always return full value. A documented professional repair from a reputable HVAC contractor can be enough, depending on the market and condition of the home.

There is one important caveat: do not keep repairing an unsafe system. A furnace with combustion problems, rollout issues, or a cracked heat exchanger is not a candidate for “just one more winter.” That is not thrift. That is gambling with worse odds than a gas station sushi buffet.

When replacement starts to look like the grown-up choice

Replacement becomes more compelling when the system is old, inefficient, uncomfortable, expensive to repair, or unreliable at exactly the wrong times. HVAC equipment has a talent for failing during weather extremes, because that is when it works hardest. No one’s furnace politely retires on a mild Tuesday in April after leaving a handwritten note.

A major compressor failure on an older air conditioner is one of the classic replacement triggers. The compressor is the heart of the refrigerant circuit, and replacing it can be expensive. If the system uses older refrigerant, has a worn contactor, aging fan motor, corroded coil, and questionable airflow, putting a new compressor into it can feel like installing a luxury kitchen in a house with a sinking foundation.

For furnaces, heat exchanger failure is a major line in the sand. The heat exchanger separates combustion gases from the air moving through your home. When it cracks or fails, replacement is often the safer and more rational path, especially on older equipment. Some heat exchangers may be under parts warranty, but labor can still be significant, and the rest of the furnace may already be near the end of its service life.

Replacement also makes sense when comfort has never been right. If the second floor is always too hot, the back bedroom feels like a meat locker, or humidity stays high even when the AC runs constantly, the old system may be improperly sized, poorly installed, or fighting duct problems. Simply repairing a part may get the unit running again, but it will not solve the comfort issue that has been annoying you since the first mortgage payment.

This is where choosing the right air conditioning contractor matters. A replacement should not be a box swap with a handshake. The contractor should evaluate load requirements, ductwork, insulation, airflow, electrical needs, [HVAC contractor](#) venting, condensate management, and equipment compatibility. Bigger is not automatically better. Oversized air **ac repair** conditioning can short cycle, leave humidity behind, and make your home feel like a cold cave with damp socks.

The refrigerant question, also known as “why is this so expensive?”

Refrigerant has become one of the more confusing parts of the repair-versus-replacement discussion. Older systems may use refrigerants that are being phased down or phased out of production. That does not automatically mean your system must be replaced tomorrow, but it can make leak repair and recharge work more expensive.

If your air conditioner has a refrigerant leak, ask where the leak is, how it was confirmed, and whether repair is practical. “It is low, so we topped it off” is not a long-term strategy. Refrigerant does not get used up like gasoline. If it is low, it went somewhere. Unless someone opened the system, low refrigerant usually means a leak.

Leak repair can be sensible if the system is relatively young, the leak is accessible, and the rest of the equipment is in good shape. But if an older evaporator coil is leaking, the condenser is aging, and the refrigerant is costly, replacement may be a better use of funds. Recharging a leaky old system every summer is like refilling a tire every morning while refusing to look for the nail.

The environmental and regulatory side also matters, but for homeowners the practical issue is usually cost and availability. Ask your contractor for options in plain language. If the answer sounds like a chemistry lecture delivered inside a leaf blower, ask again.

Efficiency: the quiet math behind the loud equipment

An older HVAC system can still run while wasting a surprising amount of energy. That does not mean every homeowner should replace working equipment purely for efficiency. The payback depends on your climate, utility rates, current equipment, home envelope, duct condition, and how you use the system.

Air conditioners are rated by SEER or SEER2, depending on equipment and current standards. Furnaces are rated by AFUE, which estimates how much fuel becomes usable heat. Heat pumps have cooling and heating efficiency ratings. Higher efficiency equipment generally costs more upfront but can reduce monthly energy use.

The key word is “can.” A high-efficiency system connected to leaky ducts in a roasting attic will not perform like the brochure promised. Neither will a fancy furnace installed with poor airflow or bad venting. Installation quality can make or break efficiency.

If your utility bills have climbed steadily and rates have not changed enough to explain it, your HVAC system may be losing performance. Dirty coils, failing motors, poor refrigerant charge, duct leaks, and aging components can all raise operating costs. A good technician should help distinguish between a repairable performance issue and an equipment package that has simply aged out.

There is also comfort efficiency, which is not printed on a yellow label. Variable-speed blowers, two-stage compressors, modulating furnaces, and properly matched heat pumps can improve temperature consistency and humidity control. You may not get a dramatic payback on paper, but you might stop walking from a 68-degree hallway into a bedroom that feels like a baked potato.

The “one more repair” trap

Homeowners often get stuck in the emotional accounting of sunk cost. They spent \$700 last year, \$450 the year before, and now the system needs another \$950. Replacing it feels like admitting those previous repairs were a waste.

They were not necessarily a waste. They bought time. Time has value. Maybe that first repair carried you through a summer when a full replacement was not in the budget. Maybe the second repair got you past the holidays. That is real.

The problem starts when each new repair is justified by the last one. “We already put money into it” becomes the reason to put more money into it, and suddenly the old unit is wearing your wallet like a feed bag.

If your system has needed multiple service visits over two or three seasons, look at the pattern. Are these unrelated minor repairs, or is the machine entering its expensive farewell tour? A capacitor one year and a clogged drain the next is not the same as refrigerant leak, blower motor, control board, and compressor warnings in close succession.

Your technician should be willing to talk about probability, not certainty. No honest contractor can promise exactly how long an old system will last after a repair. But an experienced one can say, “This repair is reasonable,” or “I would be cautious putting that much money into this equipment,” and explain why.

Safety beats savings every time

Most HVAC decisions involve comfort and cost. Some involve safety, and those deserve a different level of urgency.

Gas furnaces and boilers need proper combustion, venting, gas pressure, and safety controls. If a technician finds flame rollout, blocked venting, severe corrosion, or a cracked heat exchanger, take it seriously. Carbon monoxide is not dramatic. It is quiet, which is precisely the problem.

Electrical issues also matter. Burned wires, failing breakers, overheating motors, and damaged disconnects should not be ignored. HVAC systems draw significant power, especially during startup. A failing electrical component can create more than a comfort problem.

Water damage is another sneaky villain. Air conditioners and high-efficiency furnaces produce condensate that must drain properly. A clogged or poorly pitched drain line can damage ceilings, flooring, walls, and equipment. Sometimes an HVAC call overlaps with plumbing, especially when drains, pumps, valves, or water lines are involved. That is why homeowners often appreciate companies that understand both plumbing and HVAC, particularly when the mystery puddle does not come with a name tag.

If you see active leaking near mechanical equipment, shut things down if needed and call for help. Whether it is condensate, a humidifier line, a water heater issue, or another plumbing leak, early leak repair usually beats discovering a soft subfloor with your sock.

The installation factor nobody brags about enough

Brand matters less than homeowners think. Installation matters more than almost anyone wants to admit.

A mid-tier system installed correctly can outperform a premium system installed carelessly. Proper sizing, duct design, refrigerant charge, airflow setup, condensate routing, venting, electrical connections, thermostat configuration, and commissioning all affect reliability and comfort.

I have seen replacement systems fail early because the old ductwork could not move enough air. The equipment was blamed, but the blower was basically trying to breathe through a cocktail straw. I have seen furnaces short cycle because they were oversized. I have seen beautiful outdoor AC units set against dryer vents, buried in mulch, or squeezed into corners with poor airflow, which is like asking a marathon runner to compete while wearing a sleeping bag.

A professional replacement estimate should include more than equipment model numbers. It should discuss your home. How many square feet? What insulation? Any additions? Finished basement? Big west-facing windows? Ducts in attic or conditioned space? Hot and cold rooms? Existing electrical capacity? Drain options? Local code requirements?

If the estimate process takes seven minutes and involves no measurements, no questions, and no look at the ductwork, that is not efficiency. That is guessing with a clipboard.

Repair versus replacement during a remodel or home upgrade

Sometimes the HVAC decision arrives during a larger project. Maybe you are finishing a basement, adding a sunroom, upgrading insulation, replacing windows, or renovating a kitchen. These changes can alter heating and cooling loads.

If you improve insulation and air sealing, your home may need less heating and cooling than before. If you add square footage, especially with lots of glass, you may need more capacity or a separate zone. If you move walls or

change room layouts, ductwork may need adjustments. Replacing equipment without considering those changes can lock in comfort problems for the next decade.

Plumbing upgrades can also overlap. A basement finish may require drain planning, sump considerations, gas line evaluation, or water heater changes. If you already have a local plumber or a combined mechanical contractor involved, it is worth coordinating the work. The best projects feel boring after they are done, and I mean that as a compliment. Boring means no callbacks, no mystery smells, no ceiling stains, no thermostat wars.

For homeowners looking for a single team to evaluate connected systems, a company like TruFinity Plumbing Heating & Cooling can make the process simpler, especially when HVAC, plumbing, water lines, drains, and comfort upgrades all seem to be holding a family meeting in the utility room.

What to ask before approving a repair

A good repair decision starts with better questions. You do not need to become a refrigeration engineer by Friday, but you should understand what you are buying.

Ask the technician to show or explain the failed component, what caused the failure if known, whether other related parts tested within normal ranges, and what happens if you delay the repair. If refrigerant is involved, ask whether there is evidence of a leak and whether leak testing is recommended. If airflow is involved, ask about filter condition, coil cleanliness, static pressure, and duct restrictions. If heating is involved, ask about safety checks, combustion, venting, and carbon monoxide testing where applicable.

Here is the one list worth keeping handy before you authorize work:

1. What exactly failed, and how was it diagnosed?
2. Is this a one-time repair or part of a larger pattern?
3. What is the age and general condition of the system?
4. Are there safety concerns if I keep using it?
5. How does the repair cost compare with replacement options?

Notice what is not on that list: "Can you make it cheaper if I look sad?" You can ask, of course. It rarely hurts. But better questions usually save more money than theatrical eyebrows.

What to ask before approving a replacement

Replacement is a bigger decision, so the conversation should be more detailed. You want equipment that fits your home, not just your old concrete pad.

Ask whether the contractor performed or considered a load calculation. In residential work, Manual J is the recognized method for calculating heating and cooling loads. Not every replacement requires a full formal report in every circumstance, but the contractor should not size equipment solely by copying the old unit. The old unit may have been wrong from day one.

Ask about ductwork. If ducts are undersized, disconnected, poorly insulated, or leaking, new equipment may still disappoint you. Ask about thermostat options, zoning possibilities, filtration, humidity control, warranties, maintenance requirements, and expected installation time. Ask what is included in the quote and what could become an additional cost.

A replacement estimate should make you feel informed, not cornered. If someone says the price is good only if you sign before they leave the driveway, let them leave the driveway. Urgency is real when the heat is out during

freezing weather or the AC is dead during a heat wave. Pressure is different. Learn to smell the difference.

The timing problem: replace before failure or wait?

There is no single right answer. Replacing before total failure gives you more control. You can compare options, schedule installation during moderate weather, avoid emergency pricing, and choose equipment thoughtfully. Waiting until failure lets you squeeze full value from the old system, but you may end up making a major purchase while sweating through your shirt or sleeping under three blankets and a dog.

If your system is young or middle-aged and reliable, waiting is reasonable. Maintain it, budget for eventual replacement, and do not borrow trouble. If your system is old, inefficient, uses expensive refrigerant, and has had repeated issues, planned replacement may be the calmer path.

The best time to think about replacement is before the system fails. The worst time is when your indoor temperature has reached 86 degrees and everyone in the house has developed the personality of a wet raccoon.

The role of maintenance in delaying replacement

Maintenance will not make equipment immortal. It will, however, reduce avoidable failures and help catch small problems before they become expensive ones.

For air conditioning, maintenance usually includes checking refrigerant performance, cleaning coils as needed, inspecting electrical components, testing capacitors, clearing condensate drains, verifying temperature split, checking airflow, and making sure the outdoor unit can breathe. For heating, maintenance includes inspecting burners, ignition, flame sensing, venting, safety controls, blower operation, electrical connections, and combustion-related components.

Homeowners can help by replacing filters regularly, keeping outdoor units clear of leaves and debris, making sure supply and return vents are not blocked, and paying attention to new noises or smells. If your outdoor AC unit is surrounded by shrubs like it is hiding from creditors, trim the area. Equipment needs airflow.

Maintenance also creates a history. When a technician sees the same system year after year, they can spot trends. A motor drawing more amps than before, a capacitor weakening, rust forming in a cabinet, or temperature performance drifting can all provide early warning. That gives you time to plan instead of panic.

Edge cases that make the decision trickier

Some homes do not fit neat rules. Historic houses may have limited duct space. Additions may never have been properly tied into the original system. Townhomes and condos may have access limitations. Rural homes may rely on propane, fuel oil, heat pumps, wood stoves, or hybrid setups. In those situations, repair versus replacement may involve more than equipment age.

For example, replacing an old furnace in a tight closet might require venting changes, gas line adjustments, or condensate drainage if moving to high-efficiency equipment. Switching from an older AC to a heat pump may require electrical evaluation, thermostat changes, and careful sizing for winter performance. Replacing a system in an attic may involve access, platform, drain pan, safety switch, and code updates. None of that means replacement is bad. It means the quote should reflect the actual job, not a fantasy installation in a perfectly square laboratory house.

Budget can also shape the decision. The “best” long-term choice may not be affordable today. A reputable contractor should respect that. Sometimes the right move is a safe repair with a clear warning that replacement is

likely soon. Sometimes financing a replacement makes sense because repair costs and energy waste are stacking up. Sometimes a temporary repair is throwing money into a fan.

Good advice acknowledges real life. Mortgages, kids, medical bills, business expenses, and surprise plumbing disasters do not politely wait their turn behind HVAC decisions.

How to read the technician's recommendation

Technicians vary. Some are excellent diagnosticians. Some are better installers. Some communicate beautifully. Some speak in part numbers and sighs.

When a technician recommends repair, they should explain why the system is worth repairing. When they recommend replacement, they should explain why repair is a poor investment. You are looking for reasoning, not vibes.

Good signs include measured readings, photos, clear descriptions, options at different price points, and willingness to answer questions. Bad signs include vague doom, instant replacement talk without diagnosis, refusal to discuss repair options, or claims that every system over ten years old is basically a pumpkin.

A trustworthy contractor does not need to terrify you into making a decision. The facts should be persuasive enough.

The money conversation nobody loves but everyone needs

HVAC replacement is expensive because it involves skilled labor, equipment, materials, permits where required, disposal, electrical components, refrigerant handling, sheet metal or duct transitions, startup testing, insurance, warranties, and overhead. A proper installation is not just two people dropping off a metal box and wishing it luck.

Repair pricing also includes more than the part. You are paying for diagnosis, training, stocked vehicles, tools, licensing requirements, insurance, travel time, and the ability to get your system running when everyone else in town is also calling because the weather has turned rude.

That said, you should understand the value of what you are buying. Get a second opinion if the recommendation is costly and the situation is not an immediate safety hazard. Compare scope, not just price. One replacement quote may include duct modifications, permits, better filtration, a new thermostat, drain safety switches, and a strong labor warranty. Another may include a unit and a cheerful wave.

The cheapest quote can become the most expensive if installation is sloppy. The highest quote is not automatically the best. Look for competence, transparency, and fit.

A practical decision framework

If you want the plain-English version, here it is. Repair a younger system with an isolated, reasonably priced failure. Replace an older system when repair costs are high, breakdowns are frequent, comfort is poor, efficiency is lagging, safety is in question, or parts and refrigerant are becoming costly.

For borderline cases, ask yourself how you would feel if the same system needed another major repair next season. If the thought makes your eye twitch, replacement may be closer than you want to admit. If the repair is modest and another year or two of service would genuinely help your budget, repair may be perfectly rational.

Also consider the season. A planned heating installation in September is usually calmer than a furnace replacement during the first bitter cold snap, when every contractor's schedule looks like a dropped plate of spaghetti. The same goes for air conditioning in spring versus the first brutal heat wave.

Choose the option that solves the real problem

The real problem may be a failed part. It may be an aging system. It may be bad ductwork, poor installation, deferred maintenance, a refrigerant leak, an electrical issue, a clogged drain, or a home that has changed since the equipment was installed.

Repair versus replacement is not about being cheap or extravagant. It is about putting money where it actually helps. Sometimes that means a \$250 fix and a reminder to change the filter more often. Sometimes it means replacing a tired system before it spends another summer turning your living room into a terrarium. Sometimes it means calling a contractor who can look beyond the metal box and understand the full mechanical picture, including plumbing issues that might be contributing to the mess.

If you are staring at a noisy furnace, a sulking heat pump, or an air conditioner that has chosen interpretive dance over cooling, get a proper diagnosis first. Ask direct questions. Weigh the repair against age and condition. Think about comfort, safety, efficiency, and the likelihood of future breakdowns.

The best decision is the one that keeps your home comfortable, your family safe, and your wallet from making that small wounded noise it makes when another surprise invoice lands on the counter.

TruFinity Plumbing Heating & Cooling – Local Business Details

Kelowna

Name: TruFinity Plumbing Heating & Cooling

Address: 470 Neave Ct #104, Kelowna, BC V1V 2M2

Phone: [\(250\) 800-3811](tel:2508003811)

Website: <https://www.trufinity.ca/>

Email: service@trufinity.ca

Hours: Monday–Sunday: 24/7 emergency service; regular office hours

Open-location code: WJG5+43 Kelowna, British Columbia

TruFinity Plumbing Heating & Cooling provides plumbing, heating, cooling, drain, sewer, water quality, and indoor air quality services for homes and businesses across the Okanagan and nearby service areas.

The team serves customers through local pages for Kelowna, West Kelowna, Vernon, Penticton, and Kamloops, helping property owners find support close to their community.

For plumbing needs, TruFinity can help with repairs, fixture work, water heaters, gasfitting, inspections, and related home-service projects.

For heating and cooling, the company lists furnace, boiler, heat pump, AC, mini-split, thermostat, HVAC repair, installation, and maintenance services.

Customers looking for local service can use the Google Business Profile links for Kelowna, West Kelowna, Vernon, Penticton, and Kamloops to find the nearest TruFinity listing.

The brand's public contact information includes service@trufinity.ca and the main website at <https://www.trufinity.ca/>.

Kelowna customers can contact the local page at (250) 800-3811, while West Kelowna, Vernon, and Penticton each list dedicated local phone numbers.

TruFinity's website highlights 24/7 emergency service availability for urgent plumbing and HVAC issues, with regular office hours requiring confirmation if needed.

For the most accurate location details, customers should check the relevant map/listing URL or contact TruFinity directly before visiting a service address.

Popular Questions About TruFinity Plumbing Heating & Cooling

What services does TruFinity Plumbing Heating & Cooling provide?

TruFinity lists plumbing, heating, cooling, drain and sewer, water and air quality, and construction-related services. Common services include plumbing repairs, water heaters, gasfitting, furnace services, heat pumps, AC services, mini-splits, drain cleaning, sewer line services, and indoor air quality support.

Where does TruFinity Plumbing Heating & Cooling provide service?

TruFinity lists service-area pages for Kelowna, West Kelowna, Vernon, Penticton, and Kamloops. Customers should use the nearest location page or Google Business Profile link to confirm the best local contact option.

Does TruFinity handle both plumbing and HVAC?

Yes. TruFinity's official site lists plumbing as well as heating and cooling services, including furnace, boiler, heat pump, AC, mini-split, and thermostat services.

Does TruFinity offer emergency service?

The website states that TruFinity is available around the clock for urgent plumbing and HVAC issues. Regular office hours were not clearly listed for every location and should be confirmed directly with the business.

What is the Kelowna TruFinity address?

The Kelowna location is listed as 470 Neave Ct #104, Kelowna, BC V1V 2M2. The Kelowna phone listed on the service-area page is [\(250\) 800-3811](tel:2508003811).

What is the West Kelowna TruFinity address?

The West Kelowna location is listed as 615 Keefe Rd, West Kelowna, BC V1Z 1C6. The West Kelowna phone listed on the service-area page is [\(778\) 721-8344](tel:7787218344).

What is the Vernon TruFinity address?

The Vernon location is listed as 2907 32 St #101, Vernon, BC V1T 5M2. The Vernon phone listed on the service-area page is [\(778\) 721-8375](tel:7787218375).

What is the Penticton TruFinity address?

The Penticton location is listed as 208 Ellis St #102, Penticton, BC V2A 4L6. The Penticton phone listed on the service-area page is [\(778\) 721-8308](tel:7787218308).

What is the best way to contact TruFinity Plumbing Heating & Cooling?
